SQL Cheat Sheet: Accessing Databases using Python

SQLite

Торіс	Syntax	Description	Example
connect() cursor()	<pre>sqlite3.connect() con.cursor()</pre>	Create a new database and open a database connection to allow sqlite3 to work with it. Call sqlite3.connect() to create a connection to the database INSTRUCTOR.db in the current working directory, implicitly creating it if it does not exist. To execute SQL statements and fetch results from SQL queries, use a database cursor. Call con.cursor() to create the Cursor.	<pre>1. 1 2. 2 1. import sqlite3 2. con = sqlite3.connect("INSTRUCTOR.db") Copied! 1. 1 1. cursor_obj = con.cursor() Copied!</pre>
execute()	<pre>cursor_obj.execute()</pre>	The execute method in Python's SQLite library allows to perform SQL commands, including retrieving data from a table using a query like "Select * from table_name." When you execute this command, the result is obtained as a collection of table data stored in an object, typically in the form of a list of lists.	
fetchall()	cursor_obj.fetchall()	The fetchall() method in Python retrieves all the rows from the result set of a query and presents them as a list of tuples.	<pre>1. 1 2. 2 3. 3 4. 4 5. 5 1. statement = '''SELECT * FROM INSTRUCTOR''' 2. cursor_obj.execute(statement) 3. output_all = cursor_obj.fetchall() 4. for row_all in output_all: 5. print(row_all)</pre>
fetchmany()	cursor_obj.fetchmany()	The fetchmany() method retrieves the subsequent group of rows from the result set of a query rather than just a single row. To fetch a few rows from the table, use fetchmany(numberofrows) and mention how many rows you want to fetch.	<pre>3. 3 4. 4 5. 5 1. statement = '''SELECT * FROM INSTRUCTOR''' 2. cursor_obj.execute(statement) 3. output_many = cursor_obj.fetchmany(2)</pre>
read_sql_query()read_sql_query()	read_sql_query() is a function provided by the Pandas library in Python, and it is not specific to MySQL. It is a generic function used for executing SQL queries on various database systems, including MySQL, and retrieving the results as a Pandas DataFrame.	<pre>1. 1 1. df = pd.read_sql_query("select * from instructor;", conn)</pre>
shape	dataframe.shape	It provides a tuple indicating the shape of a DataFrame or Series, represented as (number of rows, number of columns).	1. 1 1. df.shape Copied!
close()	con.close()	con.close() is a method used to close the connection to a MySQL database. When called, it terminates the connection, releasing any associated resources and ensuring the connection is no longer active. This is important	1. 1 1. con.close() Copied!

```
for managing database
                                                   connections efficiently
                                                   and preventing resource
                                                   leaks in your MySQL
                                                   database interactions.
                                                   The CREATE TABLE
                                                   statement is used to define
                                                                                 1. 1
2. 2
3. 3
                                                   and create a new table
                                                   within a database. It
                                                   specifies the table's name,
                                                                                 5.
6.
                                                                                    5
                                                   the structure of its
                                                                                    6
                 CREATE TABLE table_name (
                                                   columns (including data
CREATE
                 column1 datatype
                                                                                 1. CREATE TABLE INTERNATIONAL_STUDENT_TEST_SCORES ( <br/> <br/>
                                                   types and constraints), and
                 constraints, column2
datatype constraints, ...); any additional properties
TABLE
                                                                                2. country VARCHAR(50), <br>
3. first_name VARCHAR(50), <br>
4. last_name VARCHAR(50), <br>
                                                   such as indexes. This
                                                   statement essentially sets
                                                                                 5. test_score INT
